## Random Walks and Defining Functions

FEB 16 TH

## If we take a random walk, will we go places?

- Problem: Simulate a random walk in which a person starts of at point $o$ and at each step randomly picks a direction (left or right) and moves 1 step in that direction.
- Take a positive integer n and terminate the simulation when the walk reaches $n$ or $-n$.
- Report the average number of steps it took for the walk to terminate.
- Do this for various n and plot the results to get a sense of how rapidly the walk terminates, as a function of $n$.

## The random module

- Programs for games and simulation use randomization extensively.
- In games, you want to add an element of randomness to the obstacles or adversaries.
- In simulations (e.g., traffic simulation) you want to introduce actors into your simulation according to certain probability distribution.

## Some functions in the random module

- random. randint $(a, b)$ : return a random integer $N$ such that $\mathrm{a}<=\mathrm{N}<=\mathrm{b}$.
- random.random(): Return the next random floating point number in the range [0.0, 1.0).
- random.uniform $(a, b)$ : Return a random floating point number $N$ such that $\mathrm{a}<=\mathrm{N}<=\mathrm{b}$ for $\mathrm{a}<=\mathrm{b}$ and $\mathrm{b}<=\mathrm{N}<=\mathrm{a}$ for $\mathrm{b}<\mathrm{a}$.

## Simple Example

Problem: Write a program that takes as input a positive integer $n$ and simulates $n$ rolls of two six-sided dice. The program should report the number of times 7 appears as the sum of the outcomes of the two dice rolls.

## Solution

```
# Programmer: Sriram Pemmaraju
# Feb 13th, }201
# This program simulates the roll of two six-sided dice
# as many times as specified by the input. Then the program
# outputs the number of times }7\mathrm{ shows up as the sum of the two
# dice rolls
import random
n= int(raw_input("Enter the number of times you want the dice rolled: "))
counter = 0 # keeps track of the number of rolls
numSevens = 0 # keeps track of the number of sevens
while counter < n:
    sumRolls = random.randint (1,6) + random.randint (1,6)
    if sumRolls == 7:
        numSevens = numSevens +1
    counter = counter +1
print "The number of sevens is", numSevens
```

## Taking a single random step

import random
\# Version 1. This program starts off a person at 0 and moves \# her one step to the left or right, at random.
location $=0$
step $=$ random.randint $(0,1)$ \# returns 0 or 1, each with prob. 1/2
if step $=0$ :
step $=-1$
location = location + step
print location

## Simulating the random walk

import random
\# Version 2. This program starts off a person at 0 and moves
\# her left or right, at random one step at a time until she reaches
\# the "barrier" at $n$ or - $n$.
$n=$ input("Enter a positive integer: ")
location $=0$
\# Loop terminates when the location reaches $n$ or $-n$
while abs(location)! $n$ :
step = random.randint $(0,1) \#$ returns 0 or 1, each with prob. 1/2
if step $==0$ :
step $=-1$
location = location + step
print location

## Counting the length of the random walk

import random
\# Version 3. This program starts off a person at o and moves
\# her left or right, at random one step at a time until she reaches
\# the "barrier" at n or - n . It outputs the length of the walk.
$\mathrm{n}=\operatorname{input}($ "Enter a positive integer: ")
location $=0$ \# tracks the location of the person
length $=\mathrm{o}$ \# tracks the length of the random walk
\# Loop terminates when the location reaches n or -n
while abs(location) != n:
step = random.randint $(0,1)$ \#returns o or 1 , each with prob. $1 / 2$
if step $=0$ :

$$
\text { step }=-1
$$

location $=$ location + step
length $=$ length +1
print length

## What more is there to do?

There are two more things we need to do to solve our problem:

1. Find the average length of a walk, for a particular value $n$ of the barrier. We have to decide how many runs to take the average over.
2. Repeat this for various values of $n$ and try to understand the trend.

We need a loop around our current code to do (1) and another loop around that code to do (2).

## Defining a function

- Things have become complicated enough that we need to reorganize our code using functions.
- The plan is to define a function called randomWalk that takes $n$ (the barrier distance) as an argument and returns the length of a simulated random walk.
- We can then just call this function from the main part of the program.

## The function randomWalk

\# This function takes the barrier distance $n$ as an argument, simulates \# the random walk until it hits the barrier ( $n$ or $-n$ ), and returns the \# length of the random walk
def randomWalk( $n$ ):
location = 0 \# tracks the location of the person length $=0 \#$ tracks the length of the random walk
\# Loop terminates when the location reaches $n$ or $-n$ while abs(location)! $n$ :
step $=$ random.randint $(0,1)$ \#returns 0 or 1 , each with prob. 1/2
if step $==0$ :
step $=-1$
location = location + step length $=$ length +1
return length

## Notes about this function

- The first line of the function:

Python keyword def randomWalk( $n$ )

- The body of the function is indented.
- It is as though $n$ is input to the function.
- A function can have one or more arguments
- The last line of the function is usually a return: return length

## The rest of the program

$$
\begin{aligned}
& n=\text { input("Enter a positive integer: ") } \\
& \text { print randomWalk(n) }
\end{aligned}
$$

- randomWalk(n) is a call to the function randomWalk providing it the number $n$ that the user as input as an argument.
- In order to execute the print statement, the function call randomWalk( $n$ ) needs to be executed first.
- This means that "control" is transferred to the function and we start executing the function starting with its first line.
- The value that the function returns essentially replaces the function call.

## Averaging over 100 simulations

$n=\operatorname{input}($ "Enter a positive integer: ")
count $=0$ \# tracks the number of times the walk is repeated sum $=0$ \# sum of the lengths of the walk; needed for average while count < 100:
sum $=$ sum + randomWalk( $n$ )
count $=$ count +1
print float(sum)/100

## Making another function

\# This function repeats a random walk with barrier $n$ as many times \# as specified by the argument numRepititions and returns the length \# of the walk, averaged over all the repititions
def manyRandomWalks( $n$, numRepititions): count $=0$ \# tracks the number of times the walk is repeated sum $=0$ \# sum of the lengths of the walk; needed for average
\# Repeats the random walk as many times as specified by numRepititions while count < numRepitions:
sum $=$ sum + randomWalk(n)
count $=$ count +1
return float(sum)/100

## The rest of the program

$n=\operatorname{input}($ "Enter a positive integer: ") print manyRandomWalks(n, 100)

- The function call needs to supply arguments in the correct order, i.e., in the order specified in the function definition.
- Names in the function call have nothing to do with names in the function definition. We could have written
$m=\operatorname{input("Enter~a~positive~integer:~")~}$
print manyRandomWalks( $m, 100$ )
And the value of $m$ and the value 100 would be used for $n$ and numRepititions in the function.

## Trying this out for different barrier values

$m=10$ \# tracks the value of the barrier
\# $m$ travels through $10,20, \ldots, 100$ in this loop and we compute and print the \# average walk length for each $m$
while $m<=100$ :
print manyRandomWalks(m, 100)
$m=m+10$

## Sample output
